pravinthorat796@gmail.com rutujamalsane320@gmail.com

Abstract— The AI-Powered Placement Preparation and Guidance Platform is an integrated artificial intelligence (AI)-assisted system designed to support students throughout the placement preparation process. Students often face challenges in preparing effective resumes, identifying suitable job opportunities, understanding industry requirements, and developing the skills required for recruitment. The proposed platform aims to address these challenges by combining multiple career-support functions within a unified web-based environment. Its major features include resume analysis, skill extraction, skill-gap identification, job recommendations, interview preparation, personalized learning guidance, placement readiness assessment, and application tracking.

A central AI Career Agent is designed to coordinate specialized components responsible for resume analysis, job discovery, hiring intelligence, interview preparation, and learning recommendations. The resume analysis component focuses on extracting relevant information, such as educational qualifications, technical skills, projects, and experience, where available. Skill-gap analysis compares the skills identified in a student's profile with the requirements of selected job roles to highlight potential areas for improvement. Based on the available profile and job information, the recommendation component aims to identify relevant employment opportunities and support

students in planning their preparation activities.

The platform combines a web-based user interface, backend services, database management, and AI-based processing modules to organize placement-related information and provide a connected user experience. Application tracking is intended to help students maintain records of job applications and monitor their progress.

The proposed system seeks to reduce the fragmentation of placement preparation by connecting student profiles, job requirements, and career guidance functions within a common workflow. Its practical usefulness depends on the quality of the input data, the accuracy of resume processing, and the relevance of recommendations. The platform's functionality and effectiveness should be evaluated through appropriate testing and measurable results. The system is intended to support student decision-making and placement preparation rather than guarantee employment outcomes.

Keywords—Artificial Intelligence, Career Recommendation, Resume Analysis, Skill Gap Analysis, Interview Preparation, MultiAgent Systems, Placement Assistance.

1. Introduction

The placement process plays an important role in helping students transition from academic education to professional employment. For students pursuing technical and engineering education, campus placement provides an opportunity to demonstrate their knowledge, technical abilities, communication skills, and problemsolving capabilities to potential employers. However, preparing for placement activities requires continuous effort, proper planning, and an understanding of current industry expectations. Students must prepare effective resumes, identify suitable job opportunities, practice technical and aptitude-based assessments, improve communication skills, and prepare for different stages of the recruitment process. Managing these activities independently can be challenging, particularly for students who have limited access to personalized career guidance.

One of the major challenges faced by students is identifying the gap between their existing skills and the requirements of their desired job roles. Although students may possess academic knowledge, they may not always have the practical skills, projects, certifications, or industry-specific competencies expected by employers. Similarly, preparing a resume that clearly presents relevant qualifications and achievements can be difficult. A resume that does not highlight appropriate skills or experience may fail to communicate a candidate's suitability for a particular position. Therefore, students need effective mechanisms to evaluate their resumes, understand job requirements, and identify areas that require improvement before applying for employment opportunities.

Another challenge is the fragmentation of placement preparation resources. Resumebuilding tools, job portals, interview preparation platforms, online learning resources, and application tracking systems generally serve different purposes. Students may need to switch between multiple applications to search for jobs, learn new skills, practice interview questions, and monitor application progress. This process can make preparation less organized and may create difficulties in maintaining a clear understanding of individual career goals. An integrated platform that combines these activities can provide a more systematic approach to placement preparation.

Recent advancements in Artificial Intelligence (AI), Machine Learning (ML), and Natural Language Processing (NLP) offer opportunities to improve career guidance and recruitment preparation. These technologies can be used to extract relevant information from resumes, identify skills, compare candidate profiles with job descriptions, and generate personalized recommendations. For example, resume analysis can help organize information about a student's education, technical skills, projects, and experience. Skill-gap analysis can compare the skills identified in a student profile with those required for a selected job role. Based on this comparison, the system can recommend relevant learning topics and preparation activities. Such recommendations can assist students in planning their preparation more effectively, although their quality depends on the accuracy and relevance of the underlying data and algorithms.

The **AI-Powered Placement Preparation and Guidance Platform** is designed to address these challenges by integrating multiple placement-support functions into a unified web-based environment. The platform focuses on resume analysis, skill extraction, skill-gap identification, job recommendations, interview preparation, personalized learning guidance, placement readiness assessment, and application tracking. Instead of treating each activity as an independent task, the proposed system connects student information, job requirements, and preparation recommendations to support a more continuous career-development process.

A central AI Career Agent is proposed to coordinate specialized components responsible for different placement-related tasks. These components may support resume evaluation, job discovery, interview practice, and personalized learning recommendations. By organizing these functions through a common workflow, the platform aims to make placement preparation more accessible and easier to manage. The system can also help students identify their strengths, prioritize areas for improvement, and track their progress throughout the preparation process. The recommendations are intended to support students' decisions rather than replace their judgment or the guidance provided by placement officers and faculty members.

The proposed platform follows a web-based architecture in which the user interface, backend services, database, and AIprocessing components work together to manage placement-related information. The system is intended to provide an organized experience for students while supporting appropriate access control and responsible handling of personal information. Since resumes and career profiles may contain sensitive personal data, privacy, data security, and the reliability of AI-generated recommendations are important considerations in the design of the platform. In addition, recommendations should be interpreted carefully because job requirements may change and automated skill matching may not fully represent a candidate's capabilities.

The main objective of this research is to propose an integrated AI-assisted platform that supports students throughout the placement preparation lifecycle. The paper describes the system architecture, functional modules, methodology, and implementation approach, along with a discussion of its potential benefits and limitations. The platform's practical usefulness should be evaluated through functional testing, representative student profiles, relevant job descriptions, and measurable criteria such as resume-analysis accuracy, recommendation relevance, and successful completion of system functions. This evaluation can help

determine whether the integrated approach provides useful support for students preparing for employment opportunities.

The remainder of this paper is organized as follows: Section 2 presents the problem statement and objectives, Section 3 discusses the related literature, Section 4 describes the proposed methodology and system architecture, Section 5 presents implementation and evaluation, and the final section concludes the paper and identifies possible directions for future enhancement.

2. Problem Statement and Objectives

2.1 Problem Statement

Students preparing for campus placements often use different tools for resume creation, job searching, aptitude practice, interview preparation, and skill development. Since these activities are not always connected, students may find it difficult to determine which skills they need to improve or which job opportunities best match their current capabilities. Traditional career guidance may also provide limited personalization when student profiles, job requirements, and learning progress are not considered together.

Therefore, an integrated placement preparation platform is needed to organize these activities and provide AI-assisted analysis and recommendations. The proposed system addresses this need by combining resume analysis, skill-gap identification, job recommendations, interview preparation, and application tracking within a common platform.

2.2 Objectives

The main objectives of the AI-Powered Placement Preparation and Guidance Platform are:

1. To develop an integrated web-based platform for placement preparation and career guidance.
2. To analyze resumes and extract relevant information, including education, skills, and experience, where available.
3. To identify potential skill gaps by comparing student skills with the requirements of selected job roles.
4. To recommend relevant job opportunities based on student profiles and available job information.
5. To support interview preparation and personalized learning guidance.
6. To provide placement readiness insights and application tracking features.
7. To design a modular AI Career Agent that coordinates specialized careersupport functions.

3. Literature Review

Artificial Intelligence and Machine Learning have increasingly been explored for career recommendation, recruitment support, resume analysis, and personalized learning. Recommendation systems can use profile information, user preferences, and jobrelated attributes to identify potentially relevant career opportunities. Content-based filtering, for example, can compare a student's skills and interests with the requirements associated with particular job roles.

Resume analysis is another important area in recruitment-support systems. Automated extraction of education, skills, and experience can help organize candidate information and

support comparisons with job descriptions. However, resume formats vary considerably, and extracted information may contain errors or omissions. Consequently, automated resume analysis should be treated as decision-support functionality rather than a guarantee of candidate suitability.

Skill-gap analysis can help learners understand the differences between their existing capabilities and the skills expected for a target role. When combined with learning recommendations, this approach can provide a more structured preparation pathway. Similarly, interview preparation tools can help students practice responses and review relevant concepts before recruitment assessments.

Despite these opportunities, separate career tools may not provide a unified workflow connecting resume analysis, skill-gap identification, job discovery, interview preparation, and application tracking. The proposed platform seeks to address this integration challenge through a modular architecture coordinated by a central AI Career Agent.

4. Proposed Methodology

4.1 System Architecture

The proposed AI-Powered Placement Preparation and Guidance Platform is designed as an integrated web-based system that combines a user interface, backend services, database management, artificial intelligence modules, and specialized careersupport agents. The primary objective of the architecture is to bring multiple placement preparation activities together within a unified platform. These activities include resume analysis, skill extraction, skill-gap identification, job recommendation, interview preparation, personalized learning guidance, placement readiness assessment, and application tracking.

The architecture is organized into different logical layers to maintain modularity, simplify maintenance, and support the integration of additional features. The frontend layer provides an interface through which students, recruiters, and administrators can interact with the system according to their roles and permissions. The backend layer processes user requests, applies business rules, coordinates system modules, and manages communication between the frontend, database, and AI-processing components.

The architecture allows individual modules to be developed and maintained separately while exchanging information through defined interfaces.

Fig. 1. Overall architecture of the proposed AI-powered placement preparation and guidance platform.

As illustrated in Fig. 1, the architecture provides a conceptual representation of the relationships between the main system components. The frontend receives user input, the backend manages application logic, and

the database maintains relevant records. AI-based modules process the available information and generate outputs for the corresponding platform features. The central coordination mechanism is intended to route requests to suitable components and combine their outputs where necessary.

The modular structure also supports future expansion. Additional features, such as aptitude preparation, communication-skills assessment, recruiter analytics, and integration with external job portals, may be incorporated if appropriate interfaces and data sources are available. However, the practical performance of the platform depends on the quality of the input data, the reliability of the processing methods, and the extent to which the individual modules have been implemented and tested.

4.2 Use Case Diagram

The use case diagram represents the interaction between the proposed platform and its primary user categories: students, administrators, and recruiters. Each user category is associated with a distinct set of responsibilities. Role-based access helps organize the system's functionality and prevents users from accessing operations that do not belong to their responsibilities.

Students are the primary users of the placement preparation features. They can create and manage their profiles, provide resume information, review extracted skills, identify potential skill gaps, explore job recommendations, prepare for interviews, and monitor application progress. The platform is intended to help students understand how their existing qualifications relate to the requirements of particular job opportunities.

Administrators are responsible for managing platform information and maintaining the overall operation of the system. Depending on the implemented functionality, administrative activities may include user management, company and job-record management, reviewing platform data, and monitoring system activity. Administrative access should be restricted to authorized users and protected through appropriate authentication and authorization mechanisms.

Recruiters represent organizations that publish job opportunities and review candidate applications. The proposed recruiter functions include managing job postings, viewing applications submitted for available positions, and updating recruitment-related information.

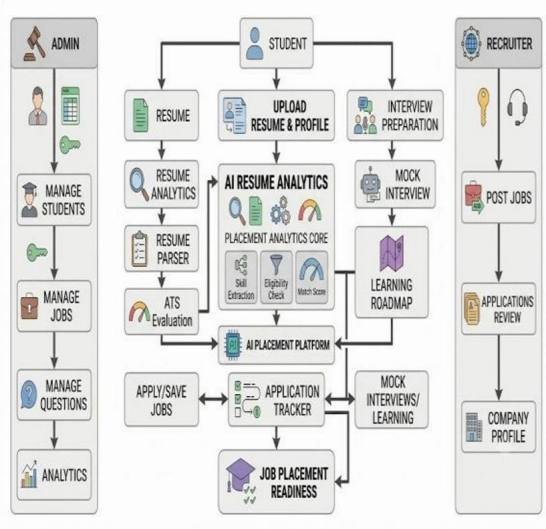

Fig. 2. Use case diagram of the proposed placement platform.

As shown in Fig. 2, the use case diagram provides a high-level view of the relationship between users and the platform's functions. It identifies the major activities available to each user category without describing every internal processing step. This separation helps clarify the responsibilities of students, recruiters, and administrators.

The student workflow begins with profile creation or profile updating. The student can then provide resume information for analysis, review the extracted skills, and explore job opportunities that may match the profile. When a job requires skills that are not clearly demonstrated in the student's profile, the platform can identify possible gaps and suggest relevant preparation activities. Students can also record application progress and review available status information.

The recruiter workflow focuses on job and candidate-related activities, while the administrator workflow focuses on managing platform records and overseeing system operations. The exact use cases included in the final diagram should match the features supported by the implementation. If any function remains at the design or prototype stage, it should be described as proposed rather than as a completed capability.

4.3 AI Career Agent and Multi-Agent Coordination

The AI Career Agent is proposed as a central coordination component that connects the platform's specialized career-support modules. Instead of treating resume analysis, job discovery, interview preparation, and learning guidance as completely separate activities, the central agent is intended to organize them into a connected workflow. It can identify the type of assistance requested and direct the request to the relevant module, subject to the system's implemented capabilities.

The proposed architecture includes specialized components such as the Resume Agent, Job Agent, Hiring Agent, Interview Agent, and Learning Agent. Each component has a defined responsibility. The Resume Agent focuses on extracting and organizing information from resumes. The Job Agent compares student profiles with available job requirements. The Hiring Agent is intended to provide relevant company or recruitment information when suitable data is available. The Interview Agent supports interview preparation, and the Learning Agent identifies potential skill gaps and suggests learning activities.

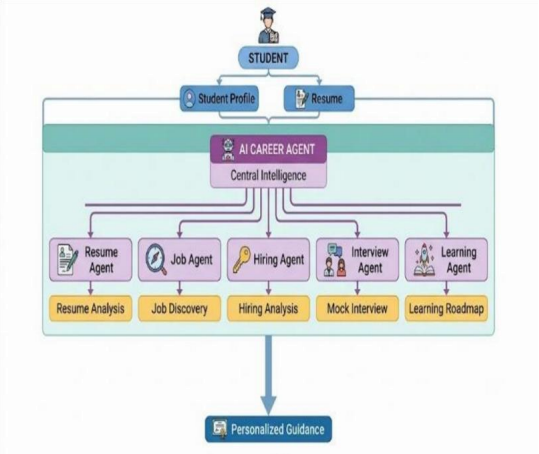

Fig. 3. Multi-agent architecture for intelligent placement assistance.

As represented in Fig. 3, the AI Career Agent coordinates requests and receives outputs from the specialized components. For example, when a student requests guidance for a particular job role, the system may first analyze the student's profile and identify relevant skills. The Job Agent can then compare those skills with the available job requirements. The Learning Agent can use the comparison to identify potential areas for improvement, while the Interview Agent can help organize preparation around the selected role.

The Resume Agent is responsible for processing resume content and identifying relevant information, such as education, technical skills, projects, certifications, and experience. The extracted information can be used to build a structured profile, subject to the accuracy of the parsing process and the

document format. Students should be able to review extracted information because automated processing may omit details or incorrectly interpret resume content.

The Job Agent is intended to identify employment opportunities that are relevant to a student's qualifications and interests. Its output depends on the availability and quality of job descriptions, the criteria used for matching, and the completeness of the student profile. A recommendation should therefore be treated as a potential match rather than a guarantee of eligibility or selection.

The Hiring Agent is designed to organize useful company and recruitment information. Its effectiveness depends on whether reliable company information is available from the system database or an authorized external source. The Interview Agent can support preparation through role-related questions, topic suggestions, or other learning resources, depending on the implemented functionality. The Learning Agent can organize suggestions around skills identified as relevant to a target role.

4.4 Resume Analysis and Skill Gap Detection

Resume analysis is an important component of the proposed platform because resume information can be used to support skill assessment and job matching. Students often prepare resumes using different formats, layouts, headings, and descriptions. These differences can make it difficult to compare resume content consistently with the requirements of a particular job role. The proposed module aims to organize relevant resume information into a structured representation for subsequent processing.

The process begins when a student provides a resume through the platform. Depending on the implemented document-processing functionality, the resume may be parsed to extract information such as educational qualifications, technical skills, projects, certifications, work experience, and other relevant details. The extracted information is then organized into a profile that can be reviewed and corrected by the student.

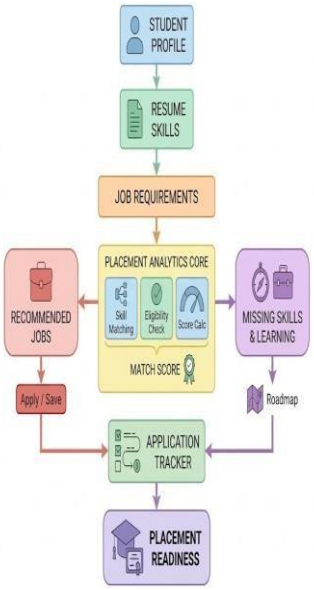

Fig. 4. Resume analysis and skill-gap detection process.

As illustrated in Fig. 4, the process consists of resume input, document parsing, information extraction, skill identification, comparison with required skills, and the generation of relevant feedback. The process may also support recommendations for resume improvement and personalized learning guidance. The quality of each stage depends on the document format, the extraction technique, and the accuracy of the information provided by the student.

After identifying the skills present in the resume, the platform can compare them with the skills associated with a selected job

description or target role. The comparison helps identify skills that appear to be present, skills that may need further development, and requirements for which there is insufficient information. For example, if a job description specifies Java, SQL, and REST API development, the system may compare these requirements with the skills and project descriptions extracted from the student's resume.

A skill gap represents a difference between the skills indicated in the student's profile and those listed in the selected job requirements. Such a difference should not automatically be interpreted as proof that the student lacks a skill. The skill may be present but omitted from the resume, described using different terminology, or not detected by the extraction process. Allowing students to review the results can reduce the effect of such errors.

The output of the skill-gap analysis can be used to support profile improvement and learning recommendations. For example, the platform may suggest reviewing a relevant topic, completing a practical project, or adding accurate evidence of an existing skill to the resume. These suggestions should be relevant to the selected job role and based on the information available to the system.

Resume evaluation and ATS-related feedback should also be presented carefully. Different applicant tracking systems use different processing and screening methods, so a general platform score cannot guarantee that a resume will pass every employer's screening process. The proposed module should therefore be described as a tool for identifying potential improvements rather than as a definitive measure of recruitment success.

4.5 Job Recommendation and Placement Assistance

The job recommendation component is intended to connect student profiles with available employment opportunities. Students may find it difficult to identify which vacancies are relevant to their qualifications, technical skills, projects, and career interests. The proposed module aims to organize job information and compare it with the profile data available within the platform.

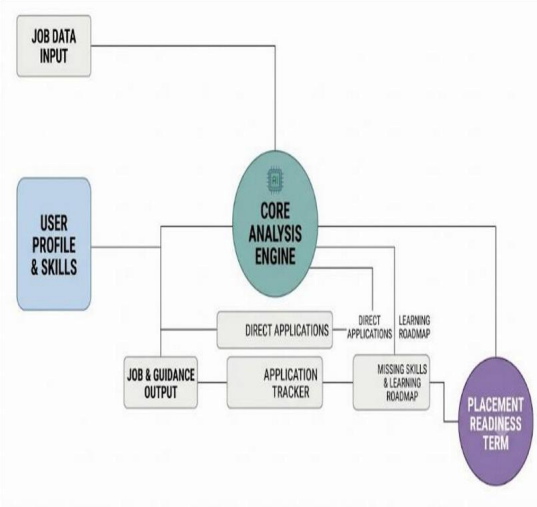

Fig. 5. Job recommendation, eligibility verification, and application-tracking workflow.

As represented in Fig. 5, the workflow connects profile information, jobrequirement analysis, job matching, eligibility-related checks, recommendation display, and application tracking. The purpose of the workflow is to help students review opportunities and organize their application activities in a single place.

The recommendation component may use rule-based matching, content-based filtering, machine-learning techniques, or a combination of methods, depending on the actual implementation. For example, a

matching process may compare the skills listed in a student profile with the skills required by a job description. Additional criteria, such as educational qualifications or experience, can be included when reliable data is available. The paper should identify the actual matching approach used rather than implying that a particular algorithm was implemented when it was not.
The system can display potentially relevant opportunities along with the information used to support each recommendation. Where possible, providing an explanation of the match can help students understand why a job was suggested and which requirements may need attention. Recommendations should not be presented as guarantees of eligibility, shortlisting, or employment because final decisions depend on employer criteria and recruitment processes.

The application-tracking component is intended to help students organize their placement activities after identifying a relevant opportunity. Depending on the implemented functionality, students may record applied jobs, review application status, monitor shortlisted opportunities, track scheduled interviews, and maintain records of recruitment outcomes. These records can help students manage their preparation and follow up on opportunities.

Application statuses should reflect the information actually entered by the student or received through a reliable integration. For example, the platform should not automatically claim that a student has been shortlisted unless that status has been provided or verified by an appropriate source. Similarly, automated updates from external recruitment portals should only be claimed if the required integration has been implemented.

By combining job recommendations with application tracking, the proposed platform aims to provide a more organized placement preparation workflow. Students can explore relevant opportunities, review potential skill gaps, prepare for interviews, and maintain application records. The overall usefulness of the workflow depends on the accuracy of student profiles, the quality of job descriptions, the relevance of the matching process, and the reliability of applicationstatus information.

4.6 Interview Preparation and Learning Guidance

The interview preparation component is intended to help students organize their preparation around a selected role, including relevant technical topics and commonly assessed skills. The learning guidance component can use identified skill gaps to suggest topics or resources for further study.

Personalized recommendations should be based on the information available to the system and should be reviewed for relevance and accuracy. If any component relies on manually curated rules or predefined content rather than an AI model, that implementation detail should be stated clearly in the final paper.

4.7 Data Management and Security

The database layer is intended to maintain student profiles, resume-related information, job records, and application progress. Authentication and authorization mechanisms should restrict access according to user roles, such as students, recruiters, and administrators, where these roles are implemented.

Because resumes can contain personal information, the platform should apply appropriate access controls and avoid exposing sensitive data to unauthorized users. Data collection, retention, and processing practices should be documented according to the actual implementation.

5. Implementation and Evaluation

The AI-Powered Placement Preparation and Guidance Platform is developed to support students throughout their placement preparation process. The backend is implemented using Java and Spring Boot, while MySQL is used for database management. Spring Security and JSON Web Token (JWT) authentication are used to support secure access and role-based authorization. REST APIs enable communication between the application components.

The backend includes modules for user profile management, company information, skills management, interview questions, quizzes, job discovery, job applications, saved jobs, notifications, resume analysis, resume matching, skill-gap analysis, career recommendations, application tracking, and administrative analytics. Additional backend components support interview preparation and career guidance.

Selected backend APIs and module operations were tested during development. The results indicate that the tested administrative analytics operations and the tested Job Discovery Agent request returned successful HTTP 200 responses. Authentication and access-control behavior was also checked during development.

The frontend is being developed using React and Vite. Complete integration of all frontend components with the backend and end-to-end validation of every feature remain separate evaluation activities. Therefore, the current evaluation focuses on the backend operations and functionality that have been tested rather than claiming that the entire platform has been fully validated.

5.1 Implementation Details

The backend follows a modular architecture in which individual services handle different placement-related operations. Spring Boot provides the REST API layer, and MySQL stores the application's structured data. Authentication and authorization are managed using Spring Security and JWT-based mechanisms.

The platform supports student, recruiter, and administrator roles, with access controlled according to the configured security rules. The available backend services cover profile and skills management, job and application management, interview preparation, quizzes, notifications, resume-related processing, career recommendations, and administrative analytics.

The resume-related components are designed to support resume parsing, resume analysis, skill identification, and comparison with relevant job requirements. Job discovery and recommendation components support access to job-related information and career opportunities. Other modules provide application tracking and preparation-related assistance.

The React-based frontend is intended to provide an interface for accessing these services. The implementation status of individual features depends on their current development and integration state. Accordingly, partially implemented or unintegrated features are not considered fully

operational solely because a corresponding backend module exists.

5.2 Functional Testing

Functional testing was conducted on selected backend APIs and modules to verify their behavior during development. API requests were used to examine the responses returned by the implemented services. The administrative analytics operations tested during development returned successful HTTP 200 responses. The tested Job Discovery Agent request also returned an HTTP 200 response.

Authentication and role-based access control were checked to identify and address access-related issues. Selected profile, skills, job, application, resume-related, interview-preparation, and other backend modules were also tested during development.

These observations provide evidence of functionality for the specific operations tested. However, successful API responses alone do not establish that every feature works correctly under all conditions. Further testing is required for invalid inputs, different user roles, error handling, frontend-backend integration, and complete end-to-end application workflows.

5.3 Results and Discussion

The implementation and functional testing demonstrate progress toward an integrated placement preparation platform. The backend provides a common structure for managing placement-related data and accessing services through REST APIs. The use of JWT authentication and role-based access control supports the separation of permissions for different user categories.

Successful HTTP 200 responses were observed for the tested administrative analytics operations and the tested Job Discovery Agent request. These responses indicate successful handling of those specific requests; they do not independently establish the accuracy or quality of the generated results. Other backend modules have also been tested, although a complete quantitative evaluation of all modules has not been established.

The current evaluation is primarily functional. No numerical claims are made regarding resume-parsing accuracy, job-recommendation accuracy, AI model performance, response-time benchmarks, or improvement in placement outcomes because verified measurements for these indicators are not available in the current evaluation.

Further work includes completing frontend-backend integration, validating the full student and recruiter workflows, testing the AI-related modules with representative inputs, and collecting measurable evaluation results. Such evaluation can include resume information extraction, relevance of job recommendations, API response time under defined conditions, and user feedback. These activities would provide a stronger basis for assessing the reliability and practical usefulness of the platform.

6. Conclusion

The AI-Powered Placement Preparation and Guidance Platform is designed to integrate several placement-support activities into a common workflow. Its proposed capabilities include resume analysis, skill-gap identification, job recommendations, interview preparation, learning guidance, placement readiness assessment, and application tracking. A

central AI Career Agent provides a modular approach for coordinating these functions.

The platform aims to help students organize their preparation, understand potential skill gaps, and explore opportunities aligned with their profiles. Its practical effectiveness depends on the reliability of resume processing, the quality of job information, the relevance of recommendations, and the implementation of appropriate security controls. Future evaluation should use clearly defined test cases and measurable criteria to assess the accuracy, usability, and usefulness of the system.

Acknowledgment

The authors express their sincere gratitude to Prof. Dr. S. P. Zope for guidance and support throughout the project. The authors also thank the Department of Computer
Engineering and the institute for providing the academic environment and resources required to undertake this work.
